# Locally compact spaces

Let  $X$  be a locally compact (Hausdorff) space.

- $C_0(X)$  is the algebra of continuous functions “vanishing at infinity”:  $\{x \in X : |f(x)| \geq \epsilon\}$  is compact for all  $\epsilon > 0$ .
- We turn  $C_0(X)$  into a *vector space* via pointwise operations.
- We turn  $C_0(X)$  into an *algebra* via pointwise operations.
- We give  $C_0(X)$  a *norm* via  $\|f\| = \sup_{x \in X} |f(x)|$ .
- Then  $C_0(X)$  is *complete*.
- We give  $C_0(X)$  an involution  $f \mapsto f^*$  via pointwise complex conjugation.
- $C^*$ -identity:  $\|f^*f\| = \|f\|^2$ .

# Abstract $C^*$ -Algebras

- A complex algebra  $A$ ,
- which has a *norm*,
- which is *complete*,
- which satisfies the  $C^*$ -condition:  $\|a^*a\| = \|a\|^2$ .

## Theorem (Gelfand)

*Let  $A$  be a commutative  $C^*$ -algebra. Then there is a locally compact Hausdorff space  $X$  such that  $A$  is isomorphic to  $C_0(X)$ .*

- “isomorphic” means all the structure is preserved.

# Gelfand theory

- A *character* on  $A$  is a non-zero *homomorphism*  $\phi : A \rightarrow \mathbb{C}$ .
- Characters are always continuous, indeed,  $\|\phi\| \leq 1$  always.
- The collection of all characters forms our space  $X$ , and we use the (relative) weak\*-topology to turn  $X$  into a topological space.
- Little exercise: If  $X$  is compact, then every character on  $C(X)$  is of the form: “evaluate at some point of  $X$ ”.

## Example

Let  $X$  be a non-locally compact metric space. This is a “nice” space, and we can form  $C_b(X)$  the algebra of *bounded* continuous functions. The “character space” of  $C_b(X)$  is then the *Stone-Cech compactification* of  $X$ , the largest compact space containing a dense copy of  $X$ .

## A little category theory

Suppose  $X$  and  $Y$  are compact, and  $\alpha : X \rightarrow Y$  is a continuous map. Then we get an algebra homomorphism  $\alpha^* : C(Y) \rightarrow C(X)$  given by

$$\alpha^*(f)(x) = f(\alpha(x)) \quad (f \in C(Y), x \in X).$$

### Theorem

*Let  $\phi : C(Y) \rightarrow C(X)$  be a unital  $*$ -homomorphism. Then there is a continuous map  $\alpha : X \rightarrow Y$  with  $\phi = \alpha^*$ .*

*In this way, the category of compact Hausdorff spaces and the opposite to the category of unital commutative  $C^*$ -algebras are isomorphic.*

To construct  $\alpha$ , just observe that  $\phi$ , composed with evaluation at  $x \in X$ , gives a character on  $C(Y)$ , that is, a point  $\alpha(x) \in Y$ .

## Locally compact case

Let  $C^b(X)$  be the bounded continuous functions on  $X$ . Then  $f : X \rightarrow Y$  induces a  $*$ -homomorphism  $\theta : C_0(Y) \rightarrow C^b(X)$ ;  $a \mapsto a \circ f$ .

Not every  $*$ -homomorphism arises in this way: an arbitrary  $\theta : C_0(Y) \rightarrow C^b(X)$  gives a continuous map  $f : X \rightarrow Y_\infty$  to the one-point compactification of  $Y$ .

To single out those maps which “never take the value  $\infty$ ” you need to look at “non-degenerate  $*$ -homomorphisms”:

$$\overline{\text{lin}}\{\theta(a)b : a \in C_0(Y), b \in C_0(X)\} = C_0(X).$$

Then we get:

# Multiplier algebras

The *multiplier algebra* of a  $C^*$ -algebra  $A$  is the largest  $C^*$ -algebra  $B$  which contains  $A$  as a two-sided ideal, in an “essential” way:

$$\text{For } b \in B, \quad ab = ba = 0 \quad (a \in A) \implies b = 0.$$

Write  $M(A)$  for the multiplier algebra (there are various constructions).

- If  $A = C_0(X)$  then  $M(A) = C^b(X)$ .
- If  $A = \mathcal{K}(H)$ , compact operators on a Hilbert space, then  $M(A) = \mathcal{B}(H)$ , all operators on a Hilbert space.

A  $*$ -homomorphism  $\theta : A \rightarrow M(B)$  is non-degenerate when

$$\overline{\text{lin}}\{\theta(a)b : a \in A, b \in B\} = B.$$

Then  $\theta$  extends to a  $*$ -homomorphism  $M(A) \rightarrow M(B)$  and in this way we can compose two non-degenerate  $*$ -homomorphisms, and get another non-degenerate  $*$ -homomorphism.

# Intuition

- We say that a “morphism” (a la Woronowicz)  $A \rightarrow B$  is a non-degenerate  $*$ -homomorphism  $\theta : A \rightarrow M(B)$ .
- Intuition: “This corresponds to a continuous function from the non-commutative space of  $B$  to the non-commutative space of  $A$ .”

# Motivation: semi-groups, compactifications

- A *semitopological semigroup* is a semigroup  $S$  which has a topology, such that the product map  $S \times S \rightarrow S$  is separately continuous.
- For example: take  $\mathbb{R}_\infty$  the one-point compactification of  $\mathbb{R}$ , with algebraic operations  $\infty + t = t + \infty = \infty$ .
- E.g. let  $S$  be a sub-semigroup of the semigroup of contractive linear maps on a Hilbert space.
- Or any reflexive Banach space.
- In fact, all compact semitopological semigroups arise in this way.

# Motivation: A tiny look at quantum groups

## Question

How do we fit a *group* into the “Gelfand” framework?

- Let  $G$  be a compact group; so have  $G \times G \rightarrow G$ .
- Same as a  $*$ -homomorphism  
 $\Delta : C(G) \rightarrow C(G \times G) = C(G) \otimes C(G)$ .
- The product is associative if and only if  $(\Delta \otimes \text{id})\Delta = (\text{id} \otimes \Delta)\Delta$ .

Let  $SC(S \times S)$  be the space of separately continuous functions on a compact space  $S$ . So for a compact semitopological semigroup, we can capture the product as a  $*$ -homomorphism  $C(S) \rightarrow SC(S \times S)$ .

## Question

How can we think of  $SC(S \times S)$  purely in terms of the commutative  $C^*$ -algebra  $C(S)$ ?

# Fubini

Fix a compact space  $X$ . Let  $M(X) = C(X)^*$  be the space of regular finite Borel measures.

## Theorem (Grothendieck)

Let  $f \in SC(X \times X)$  and  $\mu \in M(X)$ . Then

$$\begin{aligned} (\text{id} \otimes \mu)f : s &\mapsto \int_X f(s, t) d\mu(t) \\ (\mu \otimes \text{id})f : s &\mapsto \int_X f(t, s) d\mu(t) \end{aligned} \quad \text{are in } C(X).$$

For  $\lambda \in M(X)$ , we have  $\lambda((\text{id} \otimes \mu)(f)) = \mu((\lambda \otimes \text{id})(f))$ .

So each  $f \in SC(X \times X)$  well-defines a bilinear map

$$M(X) \times M(X) \rightarrow \mathbb{C}.$$

Furthermore, this is separately weak\*-continuous in each variable.

# Abstract picture of $SC(X \times X)$ , take 1

We can reverse this:

$$SC(X \times X) \cong \text{Bil}_\sigma(M(X), M(X); \mathbb{C})$$

the space of separately weak\*-continuous, bilinear maps. (For the other implication, just evaluate at points.)

- The *projective tensor product* of Banach spaces  $E, F$  is a completion of the vector space  $E \otimes F$ .
- Universal property:  $\text{Bil}(E, F; G) = \mathcal{B}(E \widehat{\otimes} F, G)$ .
- If  $A, B$  are commutative  $C^*$ -algebras, then this norm agrees with the norm on  $A^* \otimes B^*$  induced by pairing with  $A \otimes B$ , the minimal  $C^*$ -tensor product.
- So,  $(A^* \widehat{\otimes} B^*)^* = A^{**} \widehat{\otimes} B^{**}$  (consult your favourite book on tensor products of von Neumann algebras, aka  $W^*$ -algebras.)

## Abstract picture of $SC(X \times X)$ , take 2

Setting  $A = C(X)$ ,

$$SC(X \times X) = \{x \in A^{**} \overline{\otimes} A^{**} : (\mu \otimes \text{id})x, (\text{id} \otimes \mu)x \in A \ (\mu \in A^*)\}.$$

- The RHS makes sense for any  $C^*$ -algebra  $A$ .
- Do we win?
- What if  $A = \mathcal{K}(H)$ , compact operators?
- Then  $A^*$  is the trace-class operators, and  $A^{**} = \mathcal{B}(H)$ , all operators.
- So  $A^{**} \overline{\otimes} A^{**} \cong \mathcal{B}(H \otimes H)$ .
- Let  $x \in \mathcal{B}(H \otimes H)$  be the “swap map”.
- Then  $x$  slices into  $\mathcal{K}(H)$ , but  $x^2 = 1$  does not.
- So RHS is not an algebra, in general.

## From an idea from Ozawa

Let  $A$  be a unital (for convenience)  $C^*$ -algebra.

Write  $SC(A \times A) = \{x \in A^{**} \overline{\otimes} A^{**} : (\mu \otimes \text{id})x, (\text{id} \otimes \mu)x \in A \ (\mu \in A^*)\}$ .

### Theorem (D. 2014)

Let  $A \subseteq \mathcal{B}(H)$  be the universal representation, so also  $A^{**} \subseteq \mathcal{B}(H)$ . For  $x \in A^{**} \overline{\otimes} A^{**}$ , the following are equivalent:

- 1  $x, x^*x, xx^* \in SC(A \times A)$ ;
- 2  $x \in M(A \otimes \mathcal{K}(H)) \cap M(\mathcal{K}(H) \otimes A)$ ;
- 3 pick o.n. basis  $(e_i)_{i \in I}$  for  $H$ , so  $\mathcal{B}(H) \cong \mathbb{M}_I$ . Regarding  $x \in A^{**} \overline{\otimes} \mathcal{B}(H) \cong \mathbb{M}_I(A^{**})$ , we have that  $x = (x_{ij}) \in \mathbb{M}_I(A)$ , and that  $\sum_i x_{ji}x_{ij}^*$  and  $\sum_i x_{ij}^*x_{ij}$  converge in norm; and “the other way around”.

The collection of such  $x$  forms a  $C^*$ -subalgebra of  $SC(A \times A)$ , denoted  $A \overset{\text{SC}}{\otimes} A$ , which contains all other  $C^*$ -subalgebras.

# Sketch of the proof?

# For von Neumann algebras

- A  $C^*$ -algebra which is a dual space;
- equivalently, closed in the SOT on  $\mathcal{B}(H)$ .
- Commutative examples:  $L^\infty(\mu)$  for a measure  $\mu$ .
- By Gelfand,  $L^\infty(\mu) \cong C(K)$ , for a *Hyperstonian*  $K$ .
- E.g.  $\ell^\infty(\mathbb{N}) = C(\beta\mathbb{N})$  where  $\beta\mathbb{N}$  is the Stone-Cech compactification.
- Problem:  $SC(L^\infty(X) \times L^\infty(X)) \subseteq L^\infty(X)^{**} \overline{\otimes} L^\infty(X)^{**}$  which is “huge”.
- Feels like  $L^\infty(X \times X) = L^\infty(X) \overline{\otimes} L^\infty(X)$  should already be large enough to contain  $SC(K \times K)$ .
- (In fact, previous work shows it is, in the commutative case).

# Pushing down

Let  $M$  be a von Neumann algebra, with predual  $M_*$ .

- $L^\infty$  and  $L^1$  duality; or  $\mathcal{B}(H)$  and trace-class operators.
- Then  $(M_*)^* = M$  and so  $M^*$  is the *bidual* of  $M_*$ .
- So there is the canonical map  $M_* \rightarrow M^*$ , from a Banach space to its bidual.
- You can check that the Banach space adjoint,  $M^{**} \rightarrow M$ , is a (weak\*-weak\*-continuous) \*-homomorphism.
- So we get a (weak\*-weak\*-continuous) \*-homomorphism  $M^{**} \overline{\otimes} M^{**} \rightarrow M \overline{\otimes} M$ .
- Restrict this to  $\theta_{SC} : SC(M \times M) \rightarrow M \overline{\otimes} M$ .

## Some slicing

Given  $x \in M \overline{\otimes} M$ , we can always “slice” by members of  $M_*$ :

$$\langle (\mu \otimes \text{id})(x), \lambda \rangle = \langle x, \mu \otimes \lambda \rangle = \langle (\text{id} \otimes \lambda)(x), \mu \rangle.$$

This is analogous to integrating against one variable of an  $L^\infty(X \times X)$  function.

We can do something similar for  $\phi \in M^*$ :

$$\langle (\phi \otimes \text{id})(x), \mu \rangle := \langle \phi, (\text{id} \otimes \mu)(x) \rangle \quad (\mu \in M_*),$$

and similarly on the other side.

Finally, we define dual pairings between  $M^* \widehat{\otimes} M^*$  and  $M \overline{\otimes} M$ :

$$\langle \phi \otimes_{\square} \psi, x \rangle = \langle \phi, (\text{id} \otimes \psi)(x) \rangle$$

$$\langle \phi \otimes_{\diamond} \psi, x \rangle = \langle \psi, (\phi \otimes \text{id})(x) \rangle$$

# Links with weak compactness

For  $x \in M \overline{\otimes} M$ , consider the “orbit maps”

$$L_x, R_x : M_* \rightarrow M, \quad \mu \mapsto (\mu \otimes \text{id})(x), (\text{id} \otimes \mu)(x).$$

## Theorem (Arens, folklore)

*We have that  $\langle \phi \otimes_{\square} \psi, x \rangle = \langle \phi \otimes_{\diamond} \psi, x \rangle$  for all  $\phi, \psi$  if and only if  $L_x$  (equivalently,  $R_x$ ) is a weakly compact operator. Write  $\text{wap}(M \overline{\otimes} M)$  for such  $x$ .*

This is linked to the Arens products: how do we extend the product on a Banach algebra  $A$  to its bidual  $A^{**}$  such that  $A \rightarrow A^{**}$  is a homomorphism, and we have some sort of one-sided weak\*-continuity.

## Links with SC

- Given  $x \in M \overline{\otimes} M$  we might try to “lift” to some  $y \in SC(M \times M)$  such that  $\theta_{sc}(y) = x$ .
- E.g. define  $\langle y, \phi \otimes \psi \rangle = \langle \phi \otimes \square \psi, x \rangle$ .
- Or use  $\diamond$ ?

### Theorem (D.)

*This idea works if and only if  $x \in \text{wap}(M \overline{\otimes} M)$ . Indeed,  $\theta_{sc}$  maps into  $\text{wap}(M \overline{\otimes} M)$  and is a bijection between  $SC(M \times M)$  and  $\text{wap}(M \overline{\otimes} M)$ .*

We can of course restrict  $\theta_{sc}$  to  $M \overset{sc}{\otimes} M$  and so view this as the maximal subalgebra of  $\text{wap}(M \overline{\otimes} M)$ .

# Apply to $L^\infty(G)$

- Let  $G$  be a locally compact group and form  $L^1(G)$

$$\int_G |f| < \infty \quad (f * g)(s) = \int_G f(t)g(t^{-1}s) dt$$

all with respect to the (left) Haar measure.

- Then  $L^1(G)$  is a Banach algebra, and so the dual  $L^1(G)^* = L^\infty(G)$  becomes an  $L^1(G)$  module:

$$\langle f \cdot F, g \rangle = \langle F, g * f \rangle \quad (F \in L^\infty(G), f, g \in L^1(G)).$$

- Classical theory:  $F \in \text{wap}(G)$  if and only if the orbit map  $L^1(G) \rightarrow L^\infty(G); f \mapsto f \cdot F$  is weakly compact.
- Can equivalently use  $F \cdot f$ .

## Into our framework

- We have that  $L^\infty(G) \overline{\otimes} L^\infty(G) = L^\infty(G \times G)$ .
- Define  $\Delta : L^\infty(G) \rightarrow L^\infty(G \times G)$  by

$$\Delta(F)(s, t) = F(st) \quad (F \in L^\infty(G), s, t \in G).$$

- Then  $f \cdot F = (\text{id} \otimes f)\Delta(F)$  and  $F \cdot f = (f \otimes \text{id})\Delta(F)$ .
- So  $F \in \text{wap}(G)$  if and only if  $\Delta(F) \in \text{wap}(L^\infty(G) \overline{\otimes} L^\infty(G))$ .
- In this classical case, this is already an algebra.
- My motivation was to study analogues of wap for non-commutative algebras.
- So we now have a definition; just have to study it for e.g. the Fourier algebra, quantum groups etc.
